Advanced Documentation and Testing Tool (ADATT) real-world formal documentation

Formal methods are great

- complexity of hard- and software is ever increasing
- formal methods are vital to deal with this
- I'm especially interested in interactive theorem proving (ITP)
- other formal methods important as well
- amazing feats have been achieved in recent years
- very trustworthy formal models of hardware, protocols and programming languages
- verified and verifying compilers of real-world languages
- verified operating systems
- ...
- formal methods tools are powerful and even have good GUIs

ADATT ideas

- most bugs are found by
- creating a formal specification
- testing
- simple, local formal-sanity checks
- deep, complicated proofs reveal comparably few bugs
- formal method experts only needed for such deep proofs
- programmers are able and willing to write formal specifications, if
 - they are disguised as documentation, pseudo-code, tests, ...
 - it is natural and comfortable
- there is an immediate benefit for the programmer
- time is saved by
 - synergies between creating formal specifications, writing documentation and testing
 - improved communication between formal-method- and domain-experts
- progress-measures allow integration in development processes

however, they are hardly used

Formal methods are hardly used

- even critical, very well funded projects hardly use interactive theorem proving
- distinction between automatic and interactive tools is blurred
- fully automated tools usually
- are better accepted and more frequently used
- but lack in expressive power and scalability

reasons for this lack of usage are some issues, but also prejudice against formal methods

Prejudice

Even highly skilled, clever computer scientists believe:

"Interactive theorem proving and formal methods are a form black magic: they are way to complicated for mere mortals and while huge gains are luring, you need to sell your soul for these gains."

Issues with formal methods

- math, logic, proofs, etc. are complicated
- formal methods experts are needed
- it takes a lot of time

- coverage
- simple statistics
- keeping track of run tests, previous bugs, ...

ADATT look and feel

- ADATT looks like a compiler for a simple functional programming language with support for
- writing documentation
- writing tests, code contracts, properties ...
- partial implementations
- ADATT can compile to
 - high-quality human readable documentation
 - executable specifications in common programming languages
- specifications for common interactive theorem provers
- code snippets in various programming languages
- for conformance testing
- import / export of data
- ...
- good user experience is vital
- good integration in common IDEs
- good error and warning messages
- simple semantics
- language is easily readable

ADATT workflow

- start with writing natural language, informal documentation
- step by step add more formal content
- function and type declaration, type signatures

• progress and benefits are hard to measure

hide formal methods

good tools can mitigate issues

Advanced Documentation and Testing Tool (ADATT)

- I'm developing a tool to mitigate these issues
- programmers and test engineers write formal specification disguised as documentation and tests
- formal method experts extend it and deal with proofs
- time saved by synergy effects
- inspired by Lem, but ADATT focuses of partial specifications

- test cases, invariants, code contracts
- executable specifications
- adding formal content added must have immediate benefit
- progress is easily measurable
- good support for partial specifications is vital
- resulting executable specifications that can be used as
- test oracle / reference implementation
- formal model whose properties can be reasoned about
- distinction between documentation, tests and specifications blurred
- designers, programmers, test engineers and formal method experts can all work with different parts of an ADATT project
